Development and External Validation of a Diagnostic Tool for the Earlier Detection of Patients with Systemic Mastocytosis Presenting in a Real-World Community Hematology Setting

George Dranitsaris,^{1,2} Heather Neuhalfen,¹ Aaron Peevyhouse,¹ Dakota Powell,³ Kerri Miller,³ Teresa Green,³ Tara Graff⁴ ¹Real World Data, Quality Cancer Care Alliance, Tacoma, WA; ²Department of Public Health, Syracuse University, NY; ³Blueprint Medicines Corporation, Cambridge, MA; ⁴Mission Cancer and Blood, Des Moines, IA, USA

Introduction

- Systemic mastocytosis (SM) is a rare, clonal mast cell neopla characterized by the accumulation and activation of mast cells in varitissues and organs of the body, including the skin, bone marrow, live spleen, and gastrointestinal tract
- The excessive and uncontrolled activation of mast cells can lead wide range of symptoms, including skin lesions, flushing, itch abdominal pain, diarrhea, nausea, and muscle weakness
- Given the heterogeneous clinical presentation, part of the challenge in effective management of patients with SM is timely diagnosis
- This study sought to develop a diagnostic (Dx) algorithm or too raise clinical suspicion of SM and accelerate SM-specific diagno workup and diagnosis

Methods

- The Quality Cancer Care Alliance (QCCA) network real world datab was reviewed and 105 patients with SM who had presented prio October 1, 2022, were identified that met eligibility criteria
- A second sample of 104 patients diagnosed with blood cancers, but SM, were also identified
- Data collection consisted of patient demographic information, exis comorbidities, symptoms at presentation (including symptoms associa with mast cell activation), performance status, and standard hematole and biochemistry test outcomes
- General linear models (GLM) with a logit link function and a Berne distribution were then used to measure the association between se risk factors and a diagnosis of SM
- The likelihood ratio test was applied in a backward elimination proce (P<0.05 to retain) to select the final set of risk factors for retention in GLM model
- Nonparametric bootstrapping was applied to test the internal validity the final Dx model
- From the GLM statistical outputs, the contribution of the individual fac for an SM diagnosis was weighted with the final model coefficients
- To simplify calculations using these weights in a scoring algorithm, coefficients were transformed by multiplying each by a constant (deriv by trial and error) and then rounding to the nearest unit value
- A summary SM Dx score was then assigned to each patient by adding transformed coefficient values (points) for each risk factor t possessed
- The predictive accuracy of the final SM Dx algorithm was determined measuring the specificity, sensitivity, and area under the Receiver Operating Characteristic (ROC) curve
- External validation was then performed on a new sample of 162 paties (81 SM and 81 non-SM) who were managed through another commun oncology network (National Cancer Care Alliance - NCCA)
- The GLM model and scoring system was applied to the new patient cohort. Odds ratios with 95% confidence interval (CI) for the individ predictive factors were regenerated, as was the specificity, sensitiv positive predictive value, negative predictive value, and area under ROC curve for the scoring index
- Pearson Rho was then used to measure the correlation between patient risk score and probability of a positive SM diagnosis

>16	100%	19.0%	100%	59.3%	0.0	

- Patients with a total score >8 are considered to have a high likelihood of having SM. This is the point where clinicians should be thinking SM and order confirmatory tests
- Patients who had a positive diagnosis of SM were 3.53 times more likely than patients who did not have SM to have a risk score of at least >8 units

Conclusions

- patient quality of life and impact overall survival
- clinical suspicion and facilitate the early diagnosis of SM
- can be varied, depending on the clinical situation
- initiation of effective targeted therapies

is a 65-year-old female ting with chronic and skin rash for the veeks. The patient has blood count and ANC of d 5.0 [x 10³/μL]. The spleen is normal, and ph nodes are not ed upon examination. s the likelihood this has SM? at a base score of 10

65, subtract 3 units liarrhea, add 4 units a rash, add 5 units of 5, subtract (5/4) or

Final score: 14.75 elihood of SM: 95.4% (95% CI: 89–98)

Figure 1. Relationship between the diagnostic score and probability of SM

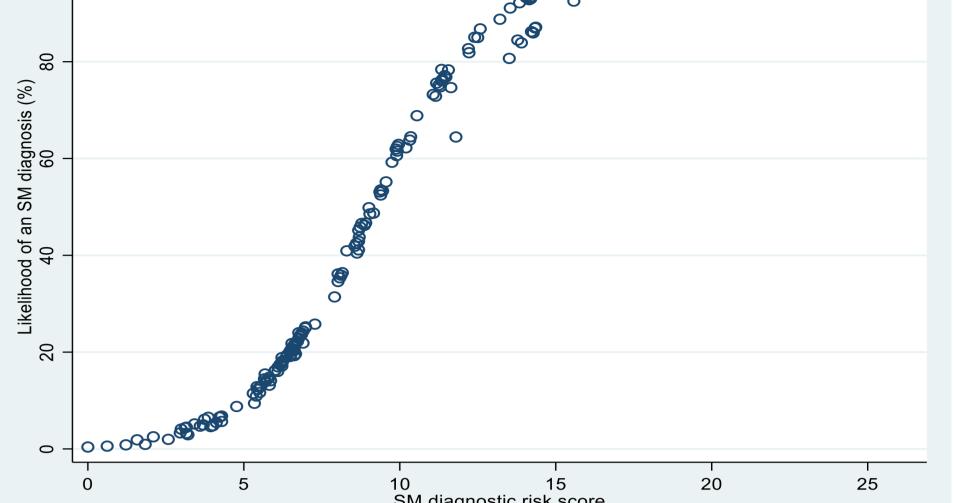

Figure 2. The area under the ROC curve in the model development cohort

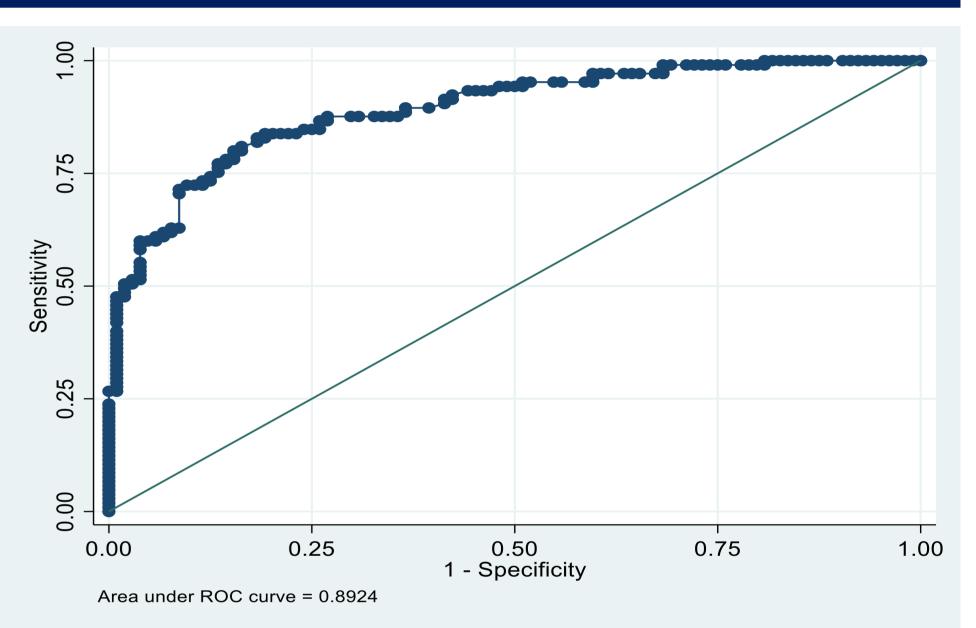

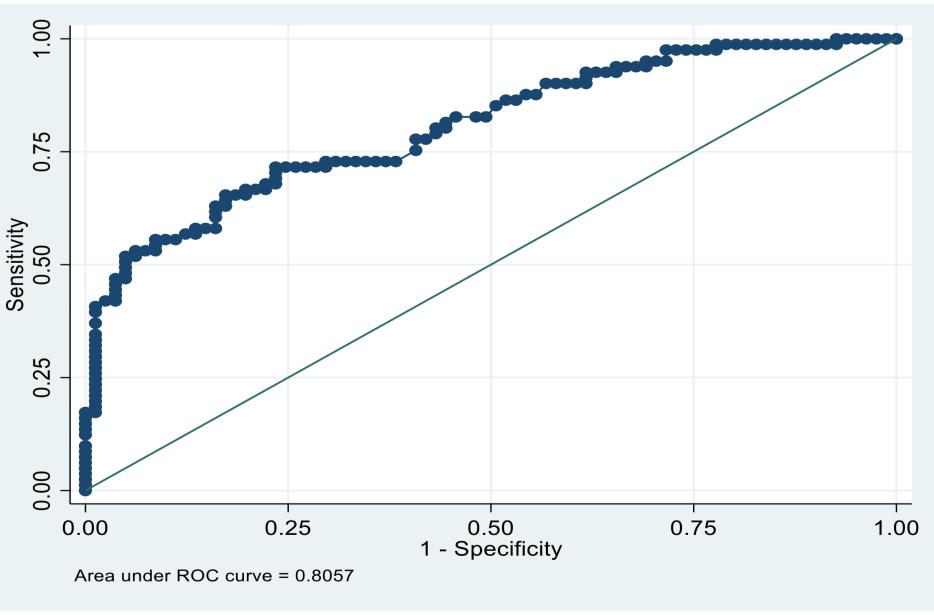

Figure 3. The area under the ROC curve in the external validation cohort

• SM is a rare disorder that may take years to diagnose. The delay in patient diagnosis can have a major impact on

• To address this need in patient care, we developed and externally validated a diagnostic tool designed to raise

• The scoring index is easy to apply, able to discriminate between patients with and without SM, and the risk threshold

• The diagnostic tool will enhance patient care by accelerating the diagnosis of SM, which would allow the timely
